During the process, This invention relates generally to digital logic circuits and more particularly to the design of domino logic circuit elements. As is well known, domino logic circuits have been extensively used to provide low-cost low-power high-density circuits. Domino logic circuits are formed from a plurality of logic circuit elements, known as P-fets, which provide input signals, or enable signals, to an output stage of the circuit. The output stage includes a complement of P-fet output logic circuits which receive the P-fet input signals in their logic inputs. In such an arrangement, the logic inputs of all of the P-fets of the circuit are connected to one input of a first set of domino logic circuits which are common to all of the P-fets. The output of the first set of common domino logic circuits is coupled to the enable input of a next set of domino logic circuits. In addition, the output stage further includes P-fet output stages which receive the P-fet input signals and provide the desired signals, such as, pulses, to the output of the circuit. The output stages of the P-fets are coupled to the complement of the output stage of the common domino logic circuits. For a detailed description of the operation of a domino logic circuit, reference is made to U.S. Pat. Nos. 4,189,706 and 4,128,899, the disclosures of which are incorporated herein by reference. In order to enable the P-fets of the low-power domino logic circuit to be reset quickly, the P-fets are typically connected in series between a high power supply and a low power supply. Thus, the P-fets can be easily reset by placing a control signal on the gate electrode of each P-fet that is common to all of the P-fets. For example, the common gate electrodes can be connected to a common gate electrode that is connected to a constant potential such as ground, except for the one element that is to be reset. The

I'm building a new ASP.NET MVC application, in which I currently have the following structure for my controllers: SiteController SearchController HomeController However, I've also got a few controllers, which are just for retrieving data, that don't have any UI on them (they just return a collection of data). These are all prefixed with a namespace and have been placed in a folder called _data, below the Controllers folder. My controllers were originally all public, but I'm now thinking that since they don't actually do anything with the UI, they should be private to the Data folder. I'm just wondering why others would insist on having controllers public? Thanks A: It depends on your MVVM pattern and the use cases you expect. I just read a very interesting article about MVVM and MVVM Part 2/3, which questions that patterns. TL;DR, the whole 3-step pattern is like the MVP pattern, but it's a pattern of couples, with M binding to View and ViewModel binding to Model: There are 3 steps to the MVVM pattern: 1) Creation - Application starts with initial state. 2) Update - State updates itself, usually using a command that is passed to the ViewModel 3) Completion - State is at the current state, and the result of the command is used by the View to draw the UI. If the model changes, the ViewModel shouldn't. Back to your question, you don't need to make your controllers public. So for example, if you have a SearchController, it should be a Controller and should work with a model. But from this model, you could execute another command (like add a new element to the model) which will update the ViewModel which will in turn update the View. netcoreapp3.1 6d1f23a050
